Abstract
Ensuring safe driving in low-light conditions heavily depends on the effectiveness of vehicle headlights. Manually adjusting headlight intensity can be distracting and often suboptimal. To address this, the Automatic Light Intensity Controller (ALIC) system for vehicles is proposed. This system employs external light sensors to continuously monitor ambient light levels. Using the sensor data, a microcontroller unit (MCU) dynamically adjusts the headlight intensity through Pulse Width Modulation (PWM) techniques. This enables automatic adaptation to changing lighting conditions, thereby enhancing driver visibility and safety. The ALIC system also provides a smart lighting solution for indoor environments, aiming to optimize energy efficiency and ensure comfortable illumination. By utilizing a light sensor, microcontroller, and control mechanism, the ALIC system dynamically adjusts the intensity of electric lights based on the surrounding ambient light. This closed-loop feedback system ensures real-time adaptation, reducing artificial light usage during periods of ample natural light and increasing it when necessary in low-light scenarios.

Introduction
With a growing emphasis on road safety and driver comfort, contemporary vehicles are integrating cutting-edge technologies to improve driving experiences. One such advancement is the Automatic Light Intensity Controller (ALIC), which adjusts the brightness of vehicle headlights based on changing ambient light levels and traffic conditions. Traditional vehicle headlights, with their fixed intensity, can often cause discomfort and danger. For instance, overly bright headlights can lead to glare, impairing the vision of oncoming drivers and increasing the risk of accidents. Conversely, insufficient lighting in dark conditions can reduce a driver's ability to see hazards on the road.

The Automatic Light Intensity Controller (ALIC) tackles these issues by offering a dynamic lighting solution. This system uses sensors to constantly monitor ambient light levels and detect the presence of oncoming vehicles. Based on the data collected, a microcontroller adjusts the headlight intensity in real-time, ensuring optimal illumination. By automatically dimming the headlights when necessary and increasing brightness in low-light conditions, this system not only enhances the driver's visibility but also significantly reduces glare for other road users.

This technology's development requires the integration of light sensors, microcontrollers, and actuator mechanisms into the vehicle's existing lighting system. The aim is to establish an autonomous, responsive lighting control system that functions without any manual input from the driver. Implementing this system is expected to enhance night-time driving safety, minimize driver fatigue, and boost overall traffic safety.
LITERATURE SURVEY
This literature survey explores the various methodologies, technologies, and design considerations involved in the development of automatic light intensity controllers for vehicles. It reviews the existing research and development efforts, highlighting the key components such as light sensors, micro-controllers, and control algorithms. Additionally, the survey examines the impact of these systems on driver safety, energy efficiency, and user comfort.

[1] In the year of 2013 by Satyendra Kumar, Praveen Kumar, Vijay Kumar published a journal called International Journal of Emerging Technology and Advanced Engineering with the title Design of Automatic Headlight Intensity Controller. This paper presents a design for an automatic headlight intensity controller based on the surrounding light conditions. It discusses the implementation of light sensors to detect ambient light levels and adjust the intensity of vehicle headlights accordingly.

[2] In the year of 2016 by M.D. Kumbhar, M.S. Ingale, and S.D. Chavan published a journal called international Journal of Scientific & Engineering Research with the title Development of Automatic Headlight Control System Based on Image Processing. This paper proposes an automatic headlight control system based on image processing techniques. It discusses the use of cameras to capture images of the road ahead and analyze them to determine the appropriate intensity of headlights based on road conditions and the presence of other vehicles.

[3] In the year of 2017 by M.S. Chandrashekara, S. S. Karthik, and M. Venugopal published a journal called International Journal of Innovative Research in Electrical, Electronics, Instrumentation and Control Engineering with the title Automatic Headlight Intensity Control System using Arduino. This paper presents a design for an automatic headlight intensity control system using Arduino micro-controllers. It discusses the implementation of light sensors and Arduino programming to adjust headlight intensity based on ambient light levels.

[5] Automatic Headlight Intensity Control using Light Dependent Resistor by S. Jadhav, Vikram Joshi and Rashmi V. Pawar Published under licence by IOP Publishing Ltd 2022. This paper proposes an Automatic dipper, a circuit which controls the intensity of the headlight of vehicle has been designed here. From this automatic dipper system, the intensity of headlight of the vehicle can be automatically controlled and can provide a better visible road using optimization techniques for light condition.

ANALYSIS AND DESIGN
A block diagram showcases a design concept for a circuit that uses light to influence an electronic component. The core of this system seems to be a light-dependent resistor (LDR) sensor. As light levels change, the resistance of the LDR sensor adjusts, potentially triggering actions in the connected circuit. The power supply, likely a 12V DC source, fuels this interaction between light and electricity. The diagram offers a glimpse into the initial stages of design, providing a road map for building a light-sensitive circuit. Energy efficient power management approach aims to pique your interest by highlighting the core functionality (light controlling electricity) and then explaining the components involved (LDR sensor, power supply) within the context of the block diagram. It also emphasizes the diagram's role as a
preliminary design concept.

**Project Architecture**

![Architectural diagram](image)

**Fig: Architecture of Light intensity control**

**Description of Architecture**

The block diagram shows the following components:

1. Power supply
2. Arduino UNO
3. Breadboard
4. LDR sensor
5. Lamp

The power supply provides power to the Arduino UNO. The Arduino UNO controls the LED lamp based on the signal from the LDR sensor. The LDR sensor detects the intensity of light. When the light intensity is low, the LDR sensor sends a signal to the Arduino UNO, which turns on the LED lamp. When the light intensity is high, the LDR sensor sends a different signal to the Arduino UNO, which turns off the LED lamp.

**Circuit Diagram**

![Circuit diagram](image)

**Fig: Circuit diagram**
Working of circuit diagram

1. LDR Sensor Connections:
   • VCC of LDR Sensor to 5V pin of Arduino: This powers the LDR sensor.
   • GND of LDR Sensor to GND pin of Arduino: This provides a common ground reference for the LDR sensor and the Arduino.
   • DO of LDR Sensor to an unspecified digital pin on Arduino: The DO pin of the LDR sensor outputs a digital signal that the Arduino can read to determine if the light level has crossed a certain threshold.

2. LED Connections:
   • Positive terminals of LEDs to Digital pins 9 and 11 of Arduino: The Arduino controls the LEDs by sending high or low signals to these pins. When the pin is high, the LED lights up; when it is low, the LED is off.
   • Negative terminals of LEDs to GND pin of Arduino: This completes the circuit for the LEDs, allowing current to flow through them when the Arduino sends a high signal to the corresponding digital pin.

3. Breadboard Connections:
   • Breadboard power rails connected to Arduino's 5V and GND pins: This allows easy distribution of power to multiple components on the breadboard.

Why These Specific Pins:
Power Pins (5V and GND): These are necessary to power the sensor and the LEDs. Digital Pins (9 and 11): These are used to control the LEDs. Digital pins: are suitable for this purpose because they can output either a high (5V) or low (0V) signal, which is perfect for turning LEDs on and off.
Ground Pins: These are needed to complete the circuits for LDR sensor and the LEDs.

Flow Chart:

Description of flow chart:
The process starts with a block labelled Start. The flowchart then goes to a decision diamond labelled Light Source. It has two paths out: one labelled Yes and the other labelled No. If there is a light source, the process continues to a block labelled Light Intensity decreases with the help of micro-controller. This suggests the micro-controller reduces the light intensity. From there, the process goes to a block labelled...
communicates with next sensing unit. This suggests the micro-controller communicates with another unit after reducing the light intensity.
If there is no light source (path labelled no), the process goes to a block labelled light intensity constant, from there, the process also goes to a block labelled communicates with next sensing unit. This suggests that even if there is no light source, the micro-controller communicates with the next sensing unit. Overall, the flowchart outlines a process for using an LDR sensor to detect light intensity and then communicating with another unit based on that reading.

**Working of the model (step wise execution)**

1. **Define the Requirements:**
   Identify the components you need, including a micro-controller (e.g., Arduino), a light sensor (LDR - Light Dependent Resistor), a relay module, and a light source (e.g., an LED).

2. **Gather Components:**
   Acquire the necessary components based on your requirements.

3. **Connect the Components:**
   Wire the components according to your circuit diagram. Connect the LDR to an analog pin on the micro-controller, and connect the relay module to a digital pin.

4. **Test the System:**
   Place the LDR in different light conditions to test if the light intensity controller responds as expected.

5. **Adjust Threshold and Parameters:**
   Fine-tune the threshold and other parameters in your code based on real-world testing.

6. **Optimize and Secure the Circuit:**
   Optimize your code for efficiency and secure the circuit by organizing and insulating components approximately.

7. **Install and Monitor:**
   Install the automatic light intensity controller in the desired location and monitor its performance over time.

**Fig: Prototype model (1)**

The figure shows prototype model of project with internal connections without power supply.
The image depicts a prototype model of an automatic light intensity controller for vehicles. This system is designed to adjust the brightness of the vehicle’s headlights based on the ambient lighting conditions, enhancing driving safety and comfort. The headlights in the model are illuminated, indicating that the system is powered and functional. The design ensures that the headlights automatically adjust their brightness to optimal levels, depending on the surrounding light conditions. This prototype serves as a proof of concept for integrating automatic light intensity control in vehicles, potentially leading to improved visibility and energy efficiency.

The image shows a circuit setup involving an Arduino, a breadboard, and an LDR (Light Dependent Resistor) sensor. The Arduino is connected to the breadboard with a red wire from the 5V pin to the positive power rail and a black wire from the GND pin to the negative power rail. The LDR is placed on the breadboard, with one leg connected to the positive power rail and the other leg connected to an analog input pin on the Arduino. Additionally, a pull-down resistor's connected between the LDR going to the analog input pin and the negative power rail to form a voltage divider circuit. This configuration enables the Arduino to read the light intensity changes detected by the LDR when there is a power flow through the circuit, providing corresponding analog voltage readings.

This configuration enables the Arduino to read the light intensity changes detected by the LDR, providing corresponding analog voltage readings.

The image shows the prototype model of an automatic light intensity controller for vehicles, specifically demonstrating the system's behaviour in dark conditions. In dark conditions, the LDR sensor detects low ambient light levels. The sensor's input is processed, and the system increases the brightness of the LED headlights. This adjustment is shown in the image, where the headlights are significantly brighter due to the dark surrounding conditions.
The image illustrates the prototype model of an automatic light intensity controller for vehicles, specifically demonstrating the system's behaviour in dim conditions. In dim conditions, the LDR sensor detects reduced ambient light levels. The sensor's input is processed, and the system adjusts the brightness of the LED headlights to this adjustment is shown in the image, where the headlights are brighter than in bright conditions but not as intense as in complete darkness. The system ensures that the headlights provide sufficient illumination in dim conditions without causing glare or consuming excessive energy. This automatic adjustment helps maintain optimal visibility and driving safety, adapting to various lighting environments effectively. This prototype demonstrates the capability of an automatic light intensity controller to adapt to different light conditions, ensuring that the road ahead is well-lit in various driving scenarios.
In brighter conditions, the Light Dependent Resistor (LDR) sensor detects high ambient light levels. The sensor's input is processed, leading the system to reduce the brightness of the LED headlights. This adjustment is illustrated in the image, where the headlights are dimmed in response to the bright surroundings. This automatic adjustment conserves energy and prevents unnecessary glare, enhancing both driving safety and comfort. The prototype effectively demonstrates how automatic light intensity control adapts to varying light conditions.

TESTING AND DEBUGGING/RESULTS

An automatic headlight intensity controller is a sophisticated automotive system designed to enhance driving safety and comfort by dynamically adjusting the brightness of a vehicle's headlights. This system typically employs sensors such as ambient light sensors, vehicle speed sensors, and potentially sensors for monitoring traffic conditions. The control logic utilizes these inputs to modulate the intensity of headlights based on various factors. During low light conditions, such as night-time or in tunnels, the system increases brightness to optimize visibility. At higher speeds, the headlights may be intensified to extend the driver's field of vision. Conversely, in well-lit urban environments or during stationary periods, the system reduces brightness to avoid glare for other drivers and conserve energy. Some advanced systems may incorporate adaptive beam control for dynamic adjustments based on road curvature and oncoming traffic. Overall, the automatic headlight intensity controller contributes to safety, energy efficiency, reduced glare, and user convenience, optimizing the driving experience across diverse conditions.

Conclusion

The Automatic Light Intensity Controller (ALIC) in vehicles greatly enhances driving safety and comfort by automatically adjusting headlight brightness based on ambient light conditions and the presence of oncoming traffic. This innovation reduces glare for other drivers and improves visibility for the driver, thereby reducing the risk of accidents. Additionally, the system promotes energy efficiency by optimizing light usage, conserving power, and extending the lifespan of lighting components. By automating headlight adjustments, it reduces the driver’s workload, allowing them to focus more on driving. Integrating this system with other vehicle technologies, such as adaptive cruise control and collision avoidance, further advances the automotive industry towards more intelligent and cohesive driving experiences. The use of sensors and advanced algorithms ensures precise and responsive adjustments, even in varying weather conditions. As the automotive industry embraces greater automation and smart technologies, the ALIC exemplifies the potential for enhancing vehicle functionality and driver safety. Future developments could incorporate machine learning to predict and adapt to a wider range of driving scenarios, making night driving safer and more efficient.

Future Scope

The future of automatic light intensity controllers in vehicles is promising, fueled by advancements in automotive technology and the demand for smarter, safer, and more energy-efficient cars. These systems will enhance safety by utilizing advanced sensors and adaptive lighting to adjust to driving conditions, speed, and road curves. They will also boost energy efficiency through sophisticated algorithms and connectivity with smart grids and IoT. Driver comfort will benefit from personalized and adaptive interior lighting. For self-driving cars, automatic light controllers will integrate with sensors and communication systems to ensure safety. Global standards will ensure the safety and reliability of these systems. With
artificial intelligence, they will continuously learn and improve. They will also be designed with eco-
friendly materials to minimize light pollution. Finally, they will work seamlessly with other advanced
systems like driver-assistance and smart traffic systems. Overall, these advancements will make automatic
light intensity controllers a crucial component of future vehicles, aligning with the automotive industry's
trends towards automation, energy efficiency, and enhanced safety and comfort.
