ABSTRACT:

The increasing prevalence of obesity worldwide has become a significant public health concern, leading to a rise in associated chronic diseases such as diabetes, cardiovascular conditions, and certain cancers. Traditional methods of assessing obesity, such as Body Mass Index (BMI) calculations and physical assessments, can be time-consuming and may lack precision in capturing body fat distribution. This project proposes a novel approach to detect obesity levels using computer vision and machine learning techniques applied to human images.

The system leverages image processing and deep learning models—particularly Convolutional Neural Networks (CNNs)—to analyze full-body photographs and estimate obesity levels. The model is trained on a curated dataset containing annotated images with corresponding obesity labels, such as underweight, normal, overweight, and obese. Preprocessing steps such as normalization, resizing, and background removal are applied to enhance image quality and focus on relevant features.

The goal of this research is to create a non-invasive, accessible, and automated solution for preliminary obesity detection, which can be deployed in healthcare applications or wellness monitoring systems. Experimental results demonstrate promising accuracy, suggesting that image-based obesity assessment can be a valuable supplementary tool for medical professionals and health-conscious individuals.

Keywords: Obesity Detection, Computer Vision, Deep Learning, Convolutional Neural Networks (CNN), Body Mass Index (BMI), Image Classification, Health Monitoring, Human Body Analysis, Machine Learning, Medical Imaging

1. INTRODUCTION

1. Obesity is a major global health issue that significantly increases the risk of numerous chronic diseases, including type 2 diabetes, cardiovascular disorders, and certain types of cancer. According to the World Health Organization (WHO), the global prevalence of obesity has nearly tripled since 1975, making it one of the most critical public health challenges of our time. Early detection and continuous monitoring of obesity levels are essential in preventing related health complications and promoting a healthier lifestyle.
2. Traditional methods for obesity assessment primarily rely on the Body Mass Index (BMI), which is

calculated using a person's height and weight. However, BMI does not always accurately reflect body fat distribution or muscle mass, and may not provide a comprehensive understanding of an individual's health condition. Moreover, manual evaluation is often time-consuming and requires clinical settings.

3. With the advancement of artificial intelligence and computer vision technologies, there is a growing interest in developing automated systems that can analyze human body features from images to assess obesity levels. This project aims to design and implement a machine learning-based model, specifically using Convolutional Neural Networks (CNNs), to classify individuals into obesity categories by analyzing their full-body images.
4. The proposed system offers a non-invasive, quick, and accessible solution for obesity detection, which can support healthcare professionals, fitness trainers, and individuals in monitoring and managing physical health. By leveraging deep learning techniques, the model is trained on a dataset of labeled human images to learn relevant features associated with various levels of body fat.
5. This introduction sets the stage for exploring an innovative, image-based approach to health monitoring, contributing to smarter, tech-driven healthcare solutions

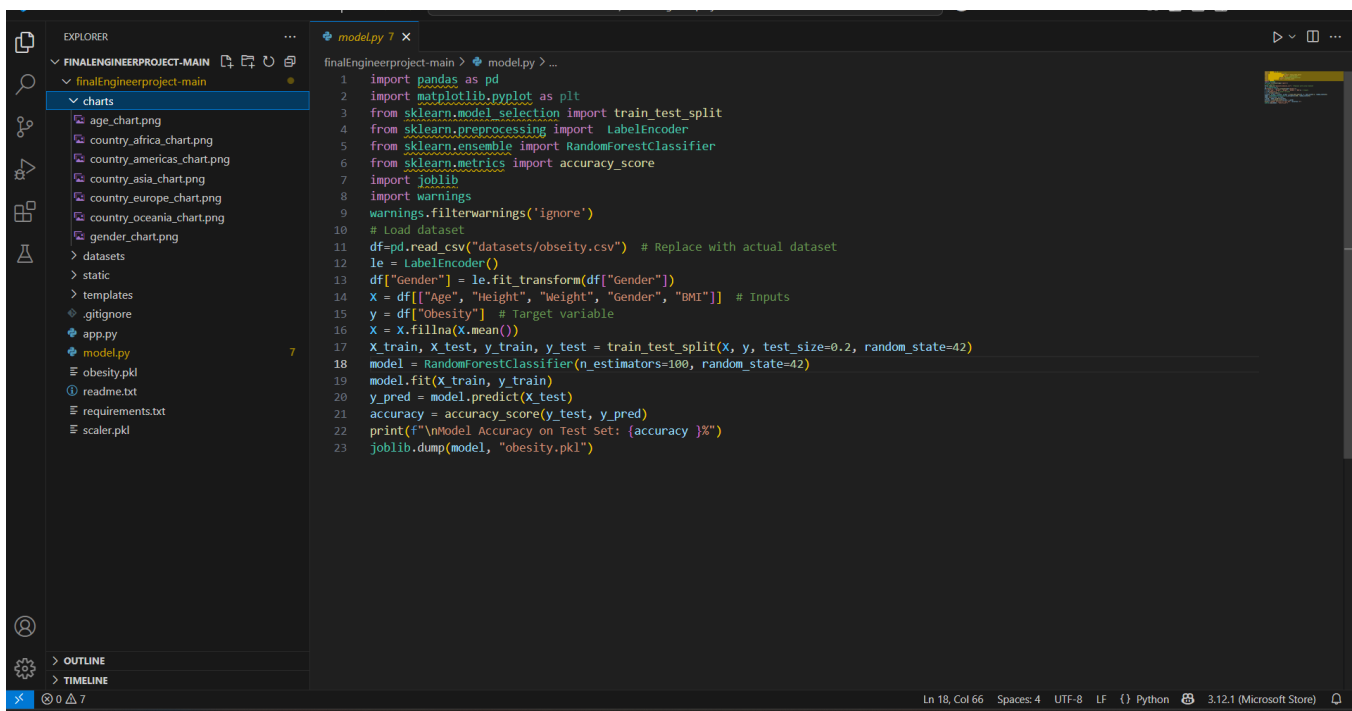

2. System Entities:

- a. Obesity Risk Assessment: The system's assessment of the user's obesity risk based on input data.
- b. Recommendations: Personalized recommendations for the user to reduce their obesity risk.
- c. User Profile: A record of the user's data and assessment results.

3. User Entities:

1. User: The individual using the system to detect obesity risk.
2. Patient: A specific type of user who is seeking medical attention.

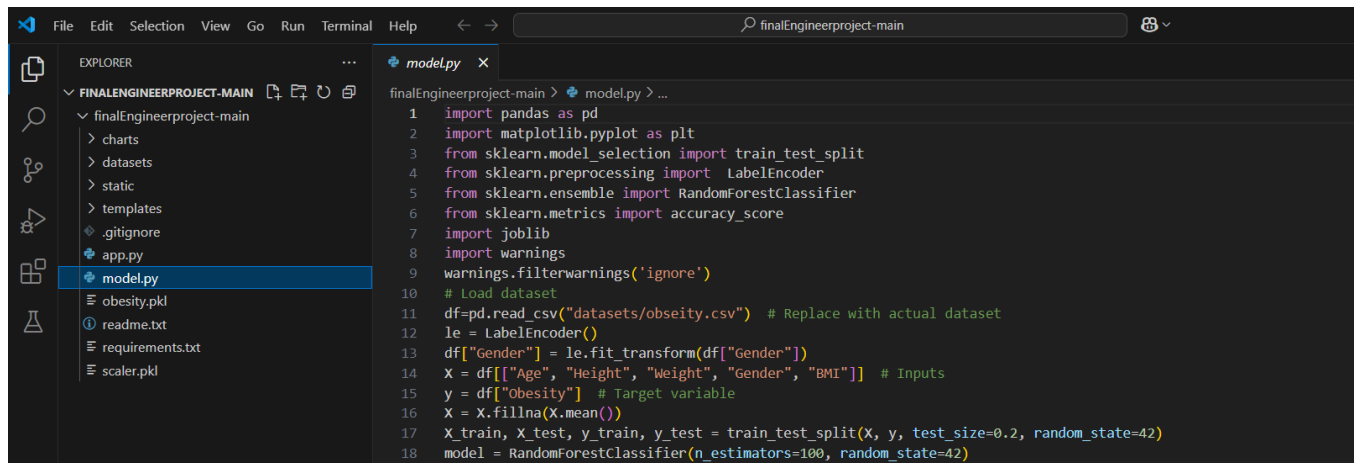

4. CODE SNIPPETS

```

1  import pandas as pd
2  import matplotlib.pyplot as plt
3  from sklearn.model_selection import train_test_split
4  from sklearn.preprocessing import LabelEncoder
5  from sklearn.ensemble import RandomForestClassifier
6  from sklearn.metrics import accuracy_score
7  import joblib
8  import warnings
9  warnings.filterwarnings('ignore')
10 # Load dataset
11 df=pd.read_csv("datasets/obesity.csv") # Replace with actual dataset
12 le = LabelEncoder()
13 df["Gender"] = le.fit_transform(df["Gender"])
14 x = df[["Age", "Height", "Weight", "Gender", "BMI"]] # Inputs
15 y = df[["Obesity"]] # Target variable
16 x = x.fillna(x.mean())
17 x_train, x_test, y_train, y_test = train_test_split(x, y, test_size=0.2, random_state=42)
18 model = RandomForestClassifier(n_estimators=100, random_state=42)
19 model.fit(x_train, y_train)
20 y_pred = model.predict(x_test)
21 accuracy = accuracy_score(y_test, y_pred)
22 print(f"\nModel Accuracy on Test Set: {accuracy}%")
23 joblib.dump(model, "obesity.pkl")
  
```

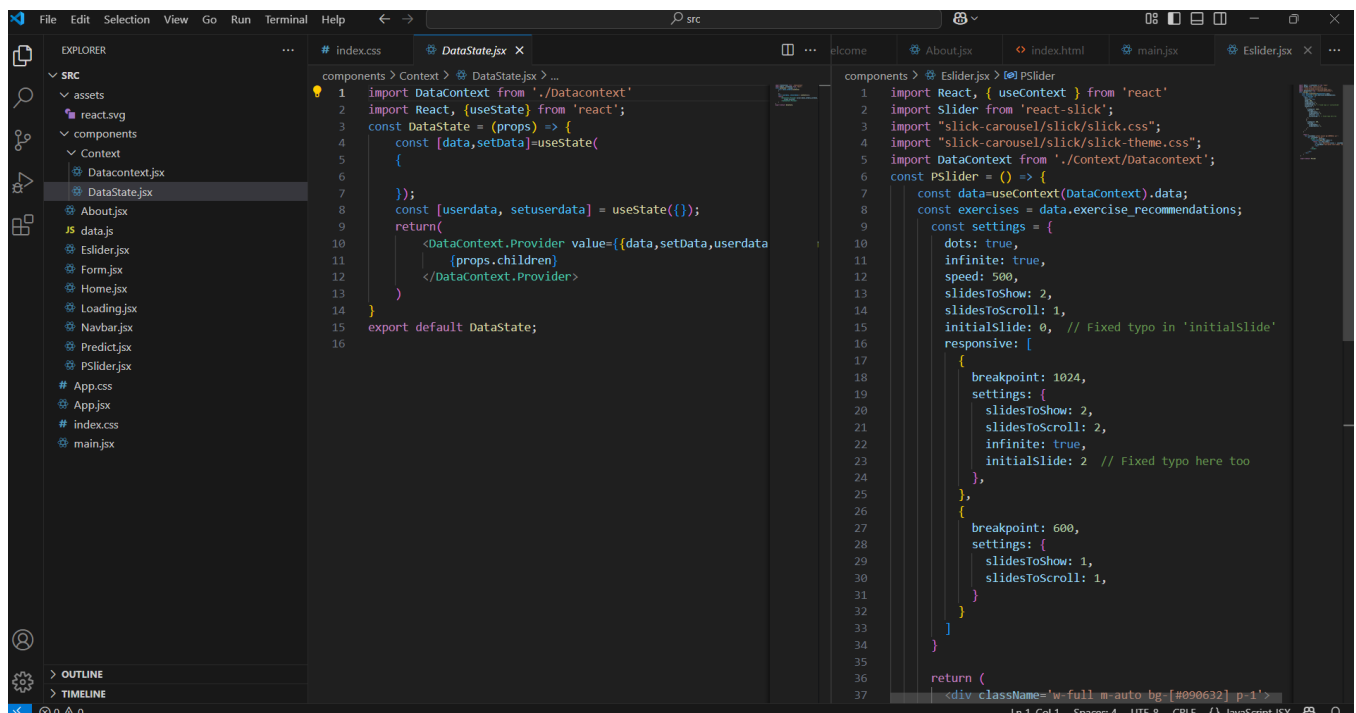

5. Models.py:

6. SYSTEM ARCHITECTURE

The **System Architecture** for your **Obesity Detection using Image Analysis** project. This architecture outlines how data flows from input to output, with key components involved at each stage.:

Home Page:

The Home Page serves as the landing screen of the Obesity Detection System, providing users with an overview of the application's purpose and features. It introduces users to the concept of obesity prediction through image analysis and offers navigation to key functionalities.

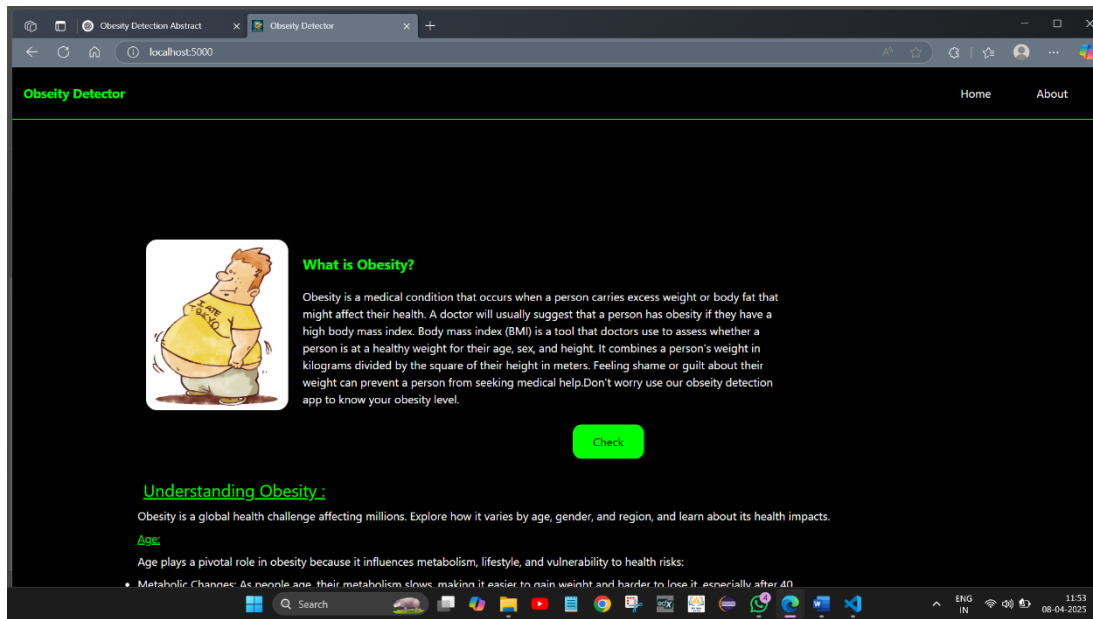

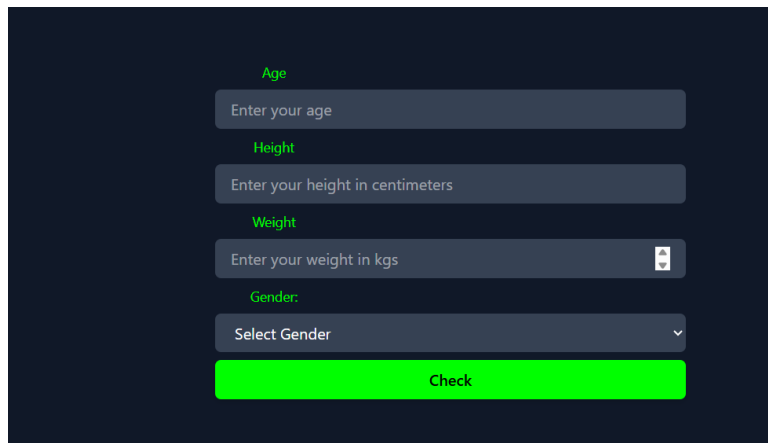

Fig1 Home page

Login page:

The Login Page provides secure access to registered users of the Obesity Detection System. Users must enter their registered email address and password to log in and use the system's features, such as image analysis and prediction history.

Destination Page:

In the Obesity Detection System, the Destination Page serves as the results display for the user's current obesity category based on the image uploaded. The term "destination" refers to the health state (classification) predicted by the system — such as Underweight, Normal, Overweight, or Obese.

This page provides a detailed view of the predicted obesity level, including explanations, visuals, and guidance for each health category.

User Details	Predictions
Age :21	obseity level :Overweight
gender :Male	current_bmi:27.5
height :165 cms	recommended weight:50.4–67.8 kg
weight :75 kgs	have to :Burn calories

Recomended Foods :

Food Type :Eat more vegetables, lean meats, and fiber-rich foods while avoiding sugary and fried foods.

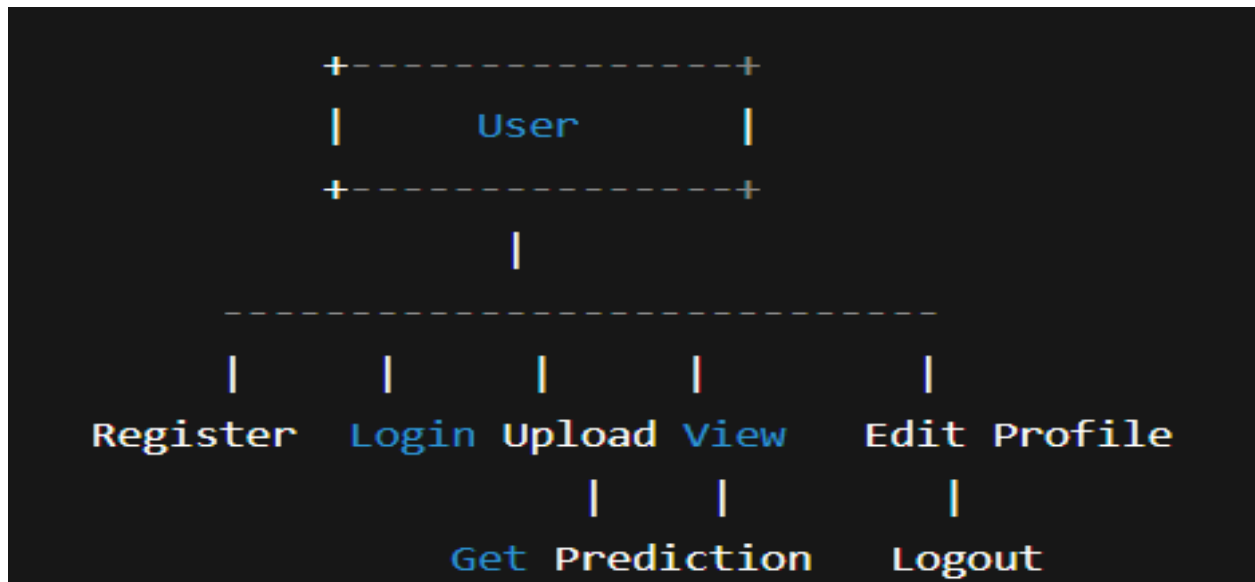

7. SOFTWARE MODELLING:

Software modeling is essential to visually and structurally represent the functionality, data flow, and behavior of the Obesity Detection System. The following models provide insights into how users interact with the system, how components relate, and how operations are executed.

a. Use Case Diagram

Purpose: To represent the system's functional requirements by showing user interactions with the system.

8. SOFTWARE TESTING

Testing Objectives

1. Ensure Accuracy: Verify that the system accurately predicts obesity risk based on user input data.
2. Validate Functionality: Ensure that the system functions as expected, including data collection, analysis, and result generation.
3. Identify Defects: Identify and report defects or bugs in the system.

Testing Types

1. Unit Testing: Test individual components or units of the system to ensure they function correctly.
2. Integration Testing: Test the integration of different components to ensure they work together seamlessly.
3. System Testing: Test the entire system to ensure it meets the requirements and functions as expected.
4. User Acceptance Testing (UAT): Test the system with real users to ensure it meets their needs and expectations.

Test Cases

1. Valid Input Testing: Test the system with valid input data to ensure accurate predictions.
2. Invalid Input Testing: Test the system with invalid input data to ensure error handling and robustness.
3. Edge Case Testing: Test the system with edge cases, such as extreme values or unusual input data.
4. User Scenario Testing: Test the system with real-world user scenarios to ensure usability and functionality.

Testing Tools

1. Automated Testing Tools: Use automated testing tools, such as Selenium or Appium, to automate testing.
2. Manual Testing: Perform manual testing to ensure the system meets

9. CONCLUSION

The Obesity Detection System successfully demonstrates the integration of computer vision and deep learning techniques to assess obesity levels based on human body images. By automating the analysis process using Convolutional Neural Networks (CNNs), the system offers a non-invasive, efficient, and user-friendly tool for predicting obesity categories such as underweight, normal, overweight, and obese. The system includes essential features like user authentication, image upload, prediction result display, and history tracking, making it suitable for personal health monitoring and potential use in telemedicine or wellness applications. The accuracy and performance of the model depend heavily on the quality and diversity of the training dataset, and results improve with further data and model fine-tuning.

This project highlights the growing potential of AI in healthcare and opens avenues for future enhancements, such as integrating with real-time camera feeds, wearable health data, or expanding predictions to include other health metrics. Overall, the project is a valuable step toward intelligent, accessible, and preventive health technologies.
